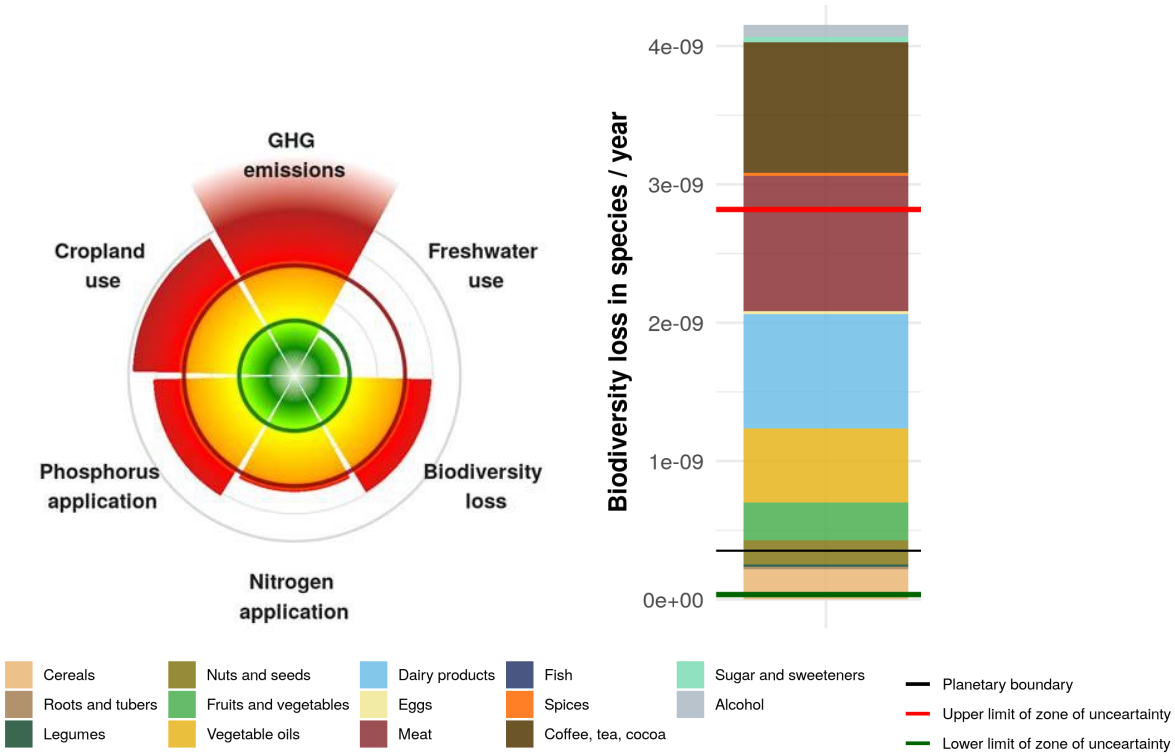
Dear Elin,

Sorry for the late response. After the workshop, we re-checked our numbers and made some changes to the calculations. The final outcome looked like this:



In the end we alsp divided the CFs by 100 assuming a time horizon of 100 years as you did.

I found the number of species considered in Chaudhary and Brooks somewhere in the SI:

species	number
plants	321212
mammals	5490
birds	10104
amphibians	6433
reptiles	9084

We tried to downscale the planetary boundary for biodiversity loss (1-80 species per million species years) to the total number of species considered here (352323) setting the lower limit at 1E-6 of this total (0.35) and the upper limit at 8E-5 (28.19).

Do you think this makes sense?

best regards,

Martin

Subject: Conversion PSL->E/MSY

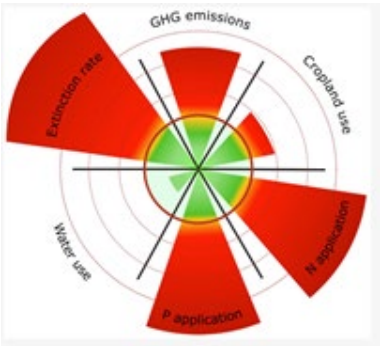
Hi Martin,

Hope all is well!

I am coming back to you regarding something we discussed during the biodiversity workshop in Gothenburg in November.

I remember I noticed the large difference in biodiversity assessment between your Austrian study:

And the one we did for Sweden:



I think one thing we concluded in Gothenburg was that we used 100 years when going from PSL->E/MSY while I think you used 20 years which would explain a lot – right?

Another thing I realized was that we used all current species in calculating the MSY (406010 species in total of mammals, birds, reptiles, amphibians and plants) while the correct thing I guess would have been to use only the species included by Chaudhary and Brooks (2018) when they calculated the characterization factors which I think you mentioned you did. However, I struggle to find this number – can you help me out?

Cheers, Elin
